

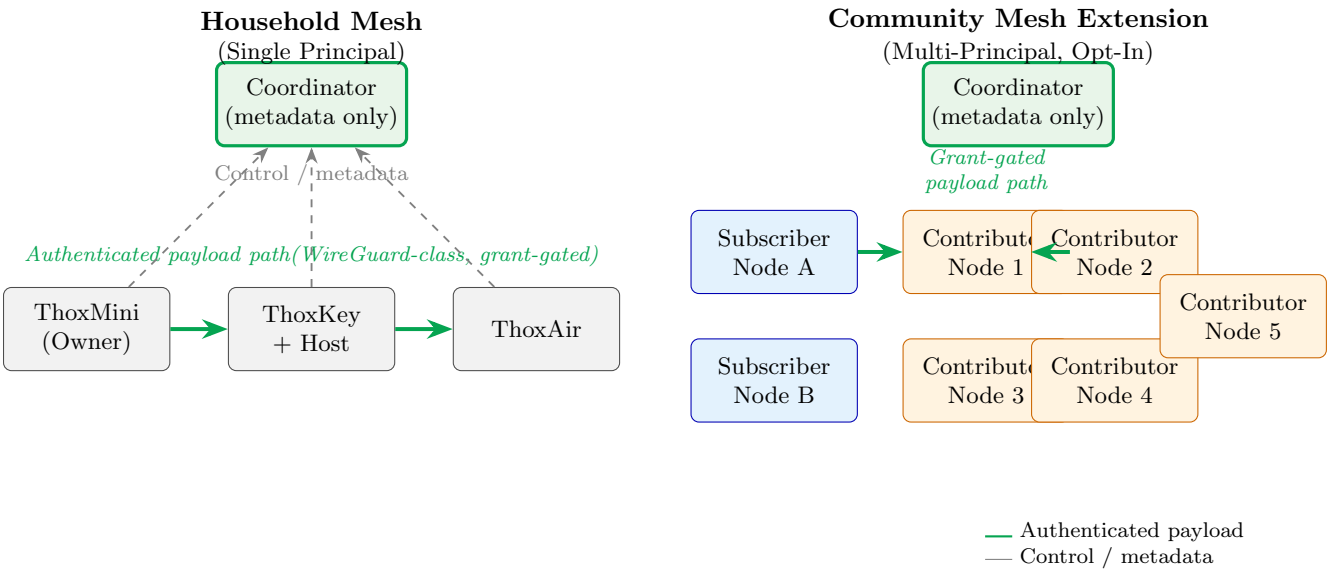

Figure 1: Household Mesh (left) versus Community Mesh Extension (right). Solid green arrows indicate authenticated, grant-gated payload paths (WireGuard-class). Dashed arrows are control and metadata only. The coordinator remains outside the payload path in both designs. Subscriber nodes (blue) and contributor nodes (orange) appear only in the multi-principal community extension. Research specification; no production community mesh claimed.

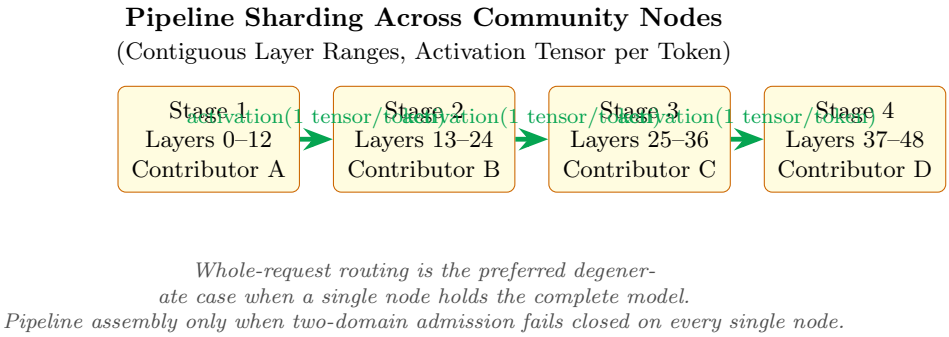

Figure 2: Pipeline sharding places contiguous layer ranges on contributor stages. One activation tensor per token crosses each boundary. Whole-request routing remains the preferred degenerate case when a single node holds the complete model. Pipeline assembly occurs only when two-domain admission fails closed on every single node. CALCULATED placement geometry from household admission rules.

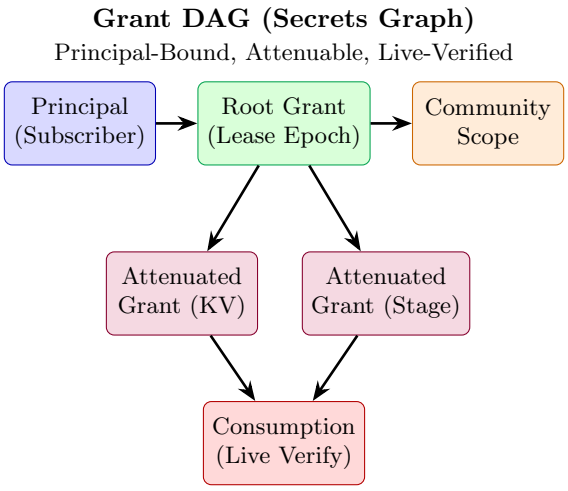

Figure 3: Grant DAG (Secrets Graph): principal-bound, attenuable grants with consumption-time validation and crypto-shredding on revocation. No cross-principal reuse. Model fingerprint must match exactly. Consumption rejects stale lease epochs.
